

Ratio Statistics

This procedure provides a variety of descriptive statistics for the ratio of two variables.

Notations

The following notation is used throughout this chapter unless otherwise stated:

n	Number of observations
A_i	Numerator of the i -th ratio ($i = 1, \dots, n$). This is usually the appraisal roll value.
S_i	Denominator of the i -th ratio ($i = 1, \dots, n$). This is usually the sale price.
R_i	The i -th ratio ($i = 1, \dots, n$). Often called the appraisal ratio.
f_i	Case weight associated with the i -th ratio ($i = 1, \dots, n$).

Data

This procedure requires for $i = 1, \dots, n$ that:

- $A_i > 0$,
- $S_i > 0$,
- $f_i > 0$, and
- w_i is a whole number. If the SPSS Weight variable contains fractional values, then only the integral parts are used.

A case is considered valid if it satisfies all four requirements above. This procedure will use only valid cases in computing the requested statistics.

Ratio Statistics

Ratio

$$R_i = \frac{A_i}{S_i}, \quad i = 1, \dots, n$$

Minimum

The smallest ratio and is denoted by R_{\min} .

Maximum

The largest ratio and is denoted by R_{\max} .

Range

The difference between the largest and the smallest ratios. It is equal to $R_{\max} - R_{\min}$.

Median

The middle number of the sorted ratios if n is odd. The mean (average) of the two middle ratios if the n is even. The median is denoted as \tilde{R} .

Average Absolute Deviation (AAD)

$$AAD = \frac{\sum_{i=1}^n f_i |R_i - \tilde{R}|}{\sum_{i=1}^n f_i}$$

Coefficient of Dispersion (COD)

$$COD = 100\% \times \frac{AAD}{\tilde{R}}$$

Coefficient of Concentration (COC)

Given a percentage $100\% \times g$, the coefficient of concentration is the percentage of ratios falling within the interval $[(1-g)\tilde{R}, (1+g)\tilde{R}]$. The higher this coefficient, the better uniformity.

Mean

$$\overline{A/S} = \bar{R} = \frac{\sum_{i=1}^n f_i R_i}{\sum_{i=1}^n f_i}$$

Standard Deviation (SD)

$$s = \sqrt{\frac{1}{(F-1)} \sum_{i=1}^n f_i (R_i - \bar{R})^2}$$

$$\text{where } F = \sum_{i=1}^n f_i.$$

Coefficient of Variation (COV)

$$COV = 100\% \times \frac{S}{R}$$

Weighted Mean

$$\overline{A/S} = \frac{\sum_{i=1}^n f_i A_i}{\sum_{i=1}^n f_i S_i} = \frac{\sum_{i=1}^n f_i S_i R_i}{\sum_{i=1}^n f_i S_i}$$

This is the weighted mean of the ratios weighted by the sales prices in addition to the usual case weights.

Price Related Differential (a.k.a. Index of Regressivity)

$$PRD = \frac{\overline{A/S}}{\overline{A/S}}$$

This is quotient by dividing the Mean by the Weighted Mean.

Property appraisals sometimes result in unequal tax burden between high-value and low-value properties in the same property group. Appraisals are considered *regressive* if high-value properties are under-appraised relative to low-value properties. On the contrary, appraisals are considered *progressive* if high-value properties are relatively over-appraised. The price related differential is a measure for measuring assessment regressivity or progressivity. Hence the price related differential is also known as the index of regressivity.

Recall that the [unweighted] mean weights the ratios equally, whereas the weighted mean high-value properties are under-appraised, thus pulling the weighted mean below the mean. On the other hand, if the PRD is less than 1, high-value properties are relatively over-appraised, pulling the weighted mean above the mean.

Confidence Interval for the Median

Distribution Free

Given the confidence level $100\% \times (1 - \alpha)$, the confidence interval for the median is an interval $(R_{[r]}, R_{[n-r+1]})$ such that

$$1 - \alpha = 1 - 2I_{0.5}(n - r + 1, r) = \frac{1}{2^n} \sum_{k=r}^{n-r} \binom{n}{k},$$

where $R_{[k]}$ is the $100\% \times k/n$ quantile, and $I_{0.5}(n - r + 1, r)$ is the incomplete Beta function.

An equivalent formula is

$$\frac{\alpha}{2} = I_{0.5}(n-r+1, r) = \frac{1}{2^n} \sum_{k=0}^{r-1} \binom{n}{k}.$$

Since the rightmost term is the cumulative Binomial distribution and it is discrete, r is solved as the largest value such that

$$\frac{\alpha}{2} \leq \frac{1}{2^n} \sum_{k=0}^{r-1} \binom{n}{k}.$$

Thus the confidence interval has coverage probability of at least $1 - \alpha$.

Normal Distribution

Assuming the ratios follow a normal distribution, a two-sided $100\% \times (1 - \alpha)$ confidence interval for the median of a normal distribution is

$$\left(\bar{R} + g_{(\alpha/2; 0.5, d)} \times s, \bar{R} + g_{(1-\alpha/2; 0.5, d)} \times s \right)$$

where $g_{(\gamma; p, d)}$ are values defined in Table 1 of Odeh and Owen (1980).

The value $g_{(\gamma; p, d)}$ is, in fact, the solution to the following equations:

$$\Pr(T_d \leq g\sqrt{n} \mid \delta = K_p\sqrt{n}) = \gamma$$

with T_d follows a noncentral Student t -distribution where d is degrees of freedom associated with the standard deviation s , δ is noncentrality parameter, γ is the probability, n is the sample size, and K_p is the upper p percentile point of a standard normal distribution.

Confidence Interval for the Mean

The normal distribution is used to approximate the distribution of the ratios. The $100\% \times (1 - \alpha)$ confidence interval for the mean is:

$$\bar{R} \pm z_{\alpha/2} \times s \times \sqrt{\frac{\sum_{i=1}^n f_i^2}{F}}$$

where $z_{\alpha/2}$ is the upper $\alpha/2$ percentage point of the standard Normal distribution, and where

$$F = \sum_{i=1}^n f_i.$$

Confidence Interval for the Weighted Mean

Using the Delta method, variance of the weighted mean is approximated as

$$\text{var}\left(\frac{\bar{A}}{\bar{S}}\right) \approx \frac{\text{var}(\bar{A})}{\bar{S}^2} - \frac{2\bar{A} \text{cov}(\bar{A}, \bar{S})}{\bar{S}^3} + \frac{\bar{A}^2 \text{var}(\bar{S})}{\bar{S}^4}.$$

where

$$\text{var}(\bar{A}) = \frac{1}{(F-1)} \sum_{i=1}^n f_i (A_i - \bar{A})^2 \times \sum_{i=1}^n f_i^2 / F^2,$$

$$\text{var}(\bar{S}) = \frac{1}{(F-1)} \sum_{i=1}^n f_i (S_i - \bar{S})^2 \times \sum_{i=1}^n f_i^2 / F^2, \text{ and}$$

$$\text{cov}(\bar{A}, \bar{S}) = \frac{1}{(F-1)} \sum_{i=1}^n f_i (A_i - \bar{A})(S_i - \bar{S}) \times \sum_{i=1}^n f_i^2 / F^2.$$
